1.7.3   Create the HTML File

Do you remember what you had to do before you could start writing HTML way back in Lesson 1? That's right—you had to create the HTML file first. Let's do that for the Privacy Policy page.

Using the command line, create a file called `privacy-policy.html` in the root of the project folder. Think back to Lessons 1 and 2 when you created files; what was the command you used?

HIDE HINT

When using the command line to create folders or files, it's easy to lose track of where you're running these commands. Don't forget to use the `pwd` command first to print out the command line's current location and confirm that the current directory is the one you want to use.

When you're done, there should be two files in the root of the project's folder: `index.html` and `privacy-policy.html`.
