6.4.7   Reflection

Nice job! You bridged the gap between two pages, `index.html` and `single-repo.html`, to create a more cohesive app. Along the way, you learned how to do the following:

- Pass information from one page to another with query parameters (much like you did with the GitHub API call).

- Read from the query string and redirect the page with the `document.location` object.

- Create a dynamic API call based on a user selection.

The next lesson will be the final one of this module. We'll build on the app's core functionality and enable users to view featured repositories based on language. This means looking into yet another GitHub API endpoint, one that will actually use multiple query parameters in a single request!
